Convert cdr to audio files.Q: In this code the signal and the controller share the same sequence I have in mind to design some pieces of electrical components to a programmable microcontroller. I'm looking at this electrical diagram to get an idea about how it works: I understand this signals are synced with the controller clock, but where they're stored in the device? In "ASIC"? Or just register? A: This is a FIFO buffer where the output is routed back to the input. It has multiple output and each one only receives one input at a time. The original Circuit Wiki article (as of August 2016) can be found here A: The clock is used for two purposes, timing and synchronization. The part you are showing is a synchronous D Flip Flop. The input will be driven high only when a clock edge (high or low) is present. This means that if any edge is present the output will be high or low. The reason why the signal is put through the buffer is that you don't want to have a 10ns delay in that region, it would make the system dead lock.
